Complementarities between Outsourcing and Foreign Sourcing

By GENE M. GROSSMAN, ELHANAN HELPMAN, AND ADAM SZEIDL*

Outsourcing has been growing both domestically and internationally. So has foreign direct investment (FDI). New models of international trade address these phenomena using recent advances in the economic theory of organizations. The models help us to identify circumstances under which firms choose to make their inputs themselves or buy them from third parties, and when they choose to produce their inputs locally or abroad (see Grossman and Helpman, 2002, 2004, 2005; Dalia Marin and Thierry Verdier, 2002, 2003; Diego Puga and Daniel Treffer, 2002; Pol Antrás, 2003; Antrás and Helpman, 2004). Some authors investigate the organizational choices of homogeneous firms in an industry with some particular characteristics while others examine the relative prevalence of different organizational structures in industries with heterogeneous firms. ¹

In this paper, we combine elements from Antrás and Helpman (2004) and Grossman et al. (2004a) to study the relationship between outsourcing and foreign sourcing (or “offshoring”). Our analysis focuses on industries with heterogeneous firms that make intensive use of intermediate inputs. Contracting problems limit the types of contracts that can be written between final producers and input suppliers. Intermediate inputs can be produced domestically or in a low-wage country and can be produced in-house or outsourced. By assumption, assembly of final goods takes place within the boundaries of the firm that has developed the product, but we sometimes allow this activity to be performed abroad.

First, we assume that assembly takes place at home and that intermediate goods can be transported at no cost. We identify conditions under which cross-industry variation in the fixed cost of outsourcing generates a positive correlation between outsourcing and foreign sourcing. We then introduce transport costs for intermediate inputs and allow firms to choose where to assemble their final output. In this case, cross-industry variation in the fixed cost of doing business abroad produces a second complementarity between outsourcing and foreign sourcing. The latter finding is in keeping with conditions described in a recent article in the Financial Times about problems facing firms producing in China (see Peter Marsh, 2004). Companies that cannot find efficient local sources for components in China are burdened with the extra costs of shipping inputs from home. Apparently, FDI often goes hand-in-hand with the ability to find suitable Chinese suppliers. The trade-offs between in-house production and outsourcing and between shipping intermediate goods and producing them in proximity to assembly operations are the subject of our investigation below.

I. The Model

There are two countries, North and South, and one factor of production, labor. The wage rate is $w^N$ in the North and $w^S$ in the South, with $w^N > w^S$. We normalize prices so that $w^N = 1$.

Consumers have Dixit-Stiglitz preferences for differentiated products that generate the inverse
demand function \( p(j) = D_j x_j(i)^{(1-\alpha)} \) for variety \( i \) of good \( j \), where \( p(j) \) is the price of this variety, \( x_j(i) \) is the quantity demanded, \( D_j \) is an index of total demand for the output of industry \( j \), and \( \alpha \) is a parameter that determines the elasticity of demand. We assume \( 0 < \alpha < 1 \), so that the elasticity of demand is larger than 1. All final goods are freely traded with zero transport costs. Thus, prices of final goods are the same in both countries and \( D_j \) measures world demand for the output of industry \( j \).

Entrepreneurs are located in the North. To enter a market and produce any variety, an entrepreneur first must incur a fixed cost of \( f_k \) units of Northern labor. An entrant then draws a productivity level \( \theta \) from a cumulative distribution \( G(\theta) \). Having learned \( \theta \), the entrepreneur decides whether and how to produce final goods or whether to exit the market.

Production requires two inputs, assembly \( a(i) \) and intermediate inputs \( m(i) \). These inputs must be specialized to variety \( i \) of product \( j \); otherwise, they cannot be combined to produce final output. Output from specialized inputs is given by

\[
x_j(i) = \theta \left[ \frac{a_j(i)}{\eta_j} \right]^{\eta_j} \left[ \frac{m_j(i)}{1 - \eta_j} \right]^{1 - \eta_j}
\]

where \( \eta_j \) is a sector-specific technological parameter. Higher values of \( \eta_j \) correspond to production technologies that make more intensive use of the assembly activity. Assembly and production of intermediate inputs can be performed in the North or in the South. One unit of \( a(i) \) or \( m(i) \) requires one unit of local labor wherever the activity is performed.

There are two types of agents, entrepreneurs who develop and assemble final goods and manufacturers who produce intermediate inputs. We use \( F \) to denote the former and \( M \) to denote the latter. Every active \( F \) agent must contract with an \( M \) agent for the supply of intermediate inputs. The \( F \) agents are located in the North, where they develop their unique brands of the final good. Some \( M \) agents are located in the North and others in the South.

In what follows, we focus on a particular industry \( j \) and omit the index \( j \) from the relevant variables. After bearing the entry cost \( f_k \) and learning his productivity \( \theta \), an \( F \) agent approaches an \( M \) agent in either the North or the South. In each location, there is an infinitely elastic supply of such agents, all of whom have an outside option normalized to zero. An \( F \) agent offers his potential partner a contract that specifies a fixed payment. The specified payment from \( F \) to \( M \) may be positive or negative, and the offer is made on a take-it-or-leave-it basis. The \( M \) agent anticipates that, if he accepts the offer, his earnings will include the contracted payment plus a fraction of profits. Profit-sharing results from \textit{ex post} bargaining once the inputs have been produced. The profit shares reflect the organization of the enterprise (see below), which \( F \) is free to choose. The \( F \) agent sets the contractual payment to provide his partner with an expected net reward of zero. All such offers are accepted.

For now we assume that assembly can be conducted only in the North. An organizational form consists of an ownership structure and a location of \( M \), denoted by \( \{k, \ell\} \), where \( k \) is either \( I \) or \( O \) (integration or outsourcing) and \( \ell \) is either \( N \) or \( S \) (North or South). The fixed cost of maintaining an organizational structure \( \{k, \ell\} \) is \( f_k^\ell \) in units of Northern labor. We assume that \( f_k^\ell \) is separable and write it as \( f_k^\ell + f_k \).

In contrast to Antràs and Helpman (2004), we assume that the fixed organizational cost of integration is less than the fixed cost of outsourcing (i.e., \( f_i < f_O \)). But like Antràs and Helpman, we assume that doing business in the

---

2 One may think about \( a \) and \( m \) as quality-adjusted effective units of the inputs rather than as quantities, with the quantity of each input normalized to 1.

3 The switch in this assumption leads to a switch in the ordering of outsourcing and integration according to productivity. While in Antràs and Helpman (2004) outsourcing is chosen by less productive firms, in our case it is chosen by more productive firms. Our assumption is appropriate when the economies of scope in management exceed the managerial overload from integration, while the reverse assumption is appropriate in the opposite case. The complementarities emphasized in this paper are clearest in the case discussed here, of separable fixed costs and more costly outsourcing.
South is more costly than doing business at home (i.e., \( f^N < f^S \)). For simplicity we also assume that \( f^N = f^S = 0 \). Thus,

\[
\begin{align*}
(2) \quad f^N_1 &< f^O_0 < f^O_0 < f^S_0 = f_0 + f^S \\
f^S_1 &< f^S_0 = f_0 + f^S.
\end{align*}
\]

Contracts are incomplete. They specify only the sizes and directions of the fixed payments, leaving the agents to bargain over surplus after the inputs have been produced. We assume Nash bargaining in which the inputs have been produced. We assume Nash bargaining in which \( \beta \in (0, 1) \) of the surplus from his relationship with \( M \). The potential revenue is \( R(i) = p(i)x(i) = Dx(i)^{\alpha} \), which, using (1), can be expressed as

\[
(3) \quad R(i) = D \theta^a \left[ \frac{a(i)}{\eta} \right]^{\alpha \eta} \left[ \frac{m(i)}{1 - \eta} \right]^{\alpha(1 - \eta)}.
\]

To determine the bargaining outcome, we need to consider the agents’ outside options. The outside option for \( M \) always is zero, because \( m(i) \) is tailored specifically to the product \( i \). Similarly, the outside option for \( F \) is zero if the organizational form involves outsourcing. However, with integration, \( F \) enjoys property rights to the inputs produced by \( M \). Since he owns these inputs, he can use them even if his partnership with \( M \) dissolves. But we assume that failure to cooperate with \( M \) is costly to \( F \); without \( M \), the entrepreneur can attain only a fraction \( \delta \) of the output described by (1). For simplicity we assume that \( \delta \in (0, 1) \) is the same in the North and the South. Therefore, under integration, \( F \) has an outside option of \( \delta aR(i) \).

Given this bargaining framework, the entrepreneur \( F \) receives the fraction \( \beta_O = \beta \) of \( R(i) \) under outsourcing and the fraction \( \beta_I = \delta a + \beta_O(1 - \delta a) \) under integration, where \( \beta_I > \beta_O \). That is, the outside option allows \( F \) to capture a larger fraction of the surplus under integration than under outsourcing. Once \( F \) selects an organizational form \( \{ k, \ell \} \), the quantity of intermediate inputs is chosen by \( M \) to maximize \( (1 - \beta_O)R(i) - w^\ell m(i) \), while the quantity of assembly is chosen by \( F \) to maximize \( \beta_I R(i) - a(i) \). We assume for the time being that intermediate inputs can be traded costlessly. In the event, operating profits for \( \{ k, \ell \} \) are given by

\[
(4) \quad \pi^f_k(\Theta) = D^{1/(1 - \alpha)} \Theta \psi_k^f - f^f_k
\]

where \( \Theta = \theta^{\alpha/(1 - \alpha)} \) is a variant of our productivity measure and

\[
\psi_k^f = \frac{1 - \alpha [\beta_k \eta + (1 - \beta_k)(1 - \eta)]}{\left( \left( \frac{1}{\alpha} \right) \left( \frac{1}{\beta_k} \right) \left( \frac{w^f}{1 - \beta_k} \right)^{1 - \eta} \right)^{\alpha(1 - \alpha)}}.
\]

As explained in Antrás and Helpman (2004), if production of final output makes sufficiently intensive use of intermediate inputs (\( \eta \) is small enough), then \( \psi_k^f \) declines with \( \beta_k \) and \( \psi_k^f < \psi_O^f \). If, on the other hand, production makes sufficiently intensive use of assembly, then \( \psi_k^f \) rises with \( \beta_k \) and \( \psi_k^f > \psi_O^f \).

Since \( F \) appropriates all of the operating profits via his choice of the contractual fixed payment, he opts for the organizational form \( \{ k, \ell \} \) that generates the largest value of \( \pi^f_k(\Theta) \). Evidently, the organizational choice varies with the productivity of the firm. Also, since the fixed cost of integration in the North is zero, no final good producer exits the market for any productivity draw.

II. Organizational Forms

We analyze the organizational choices of firms that differ in their productivity levels. Two complementarities between outsourcing and foreign sourcing are reflected in the equilibrium choices.

A. Complementarity I

In the discussion of the first complementarity, we maintain the assumption that there are no transport costs of intermediate inputs or final goods. We also assume (as we do for the remainder of the paper) that production is intensive in the use of intermediate inputs, so that operating profits are declining in \( \beta_k \). When this is true, providing better incentives for \( M \) is more important to \( F \) than is appropriating a larger
fraction of the revenue. This consideration gives outsourcing an advantage over integration. On the other hand, outsourcing entails a greater fixed cost. Thus, there is a trade-off between outsourcing and integration, which leads more productive firms to outsource and less productive firms to integrate. The more-productive firms choose to leave ownership rights to the intermediate inputs in the hands of the manufacturer, because it is profitable for them to produce larger volumes of output and they thus benefit more from preserving the incentives for M to produce large quantities of m(i).

We show in our working paper, Grossman et al. (2004b), that F agents select their organization according to the pattern depicted in Figure 1. There are four regions, {I, S}, {I, N}, {O, S} and {O, N}, each corresponding to a different organizational form. The first index describes the ownership structure, I or O, while the second describes the location of M, in N or in S. For example, {I, S} describes a vertically integrated firm that produces intermediate inputs in the South. This strategy involves foreign direct investment (FDI), because inputs are produced in a foreign subsidiary. The figure focuses on variations in productivity, Θ, and variations in the fixed cost of outsourcing, fO. The value of fO is fixed in a given industry but varies across industries. Productivity varies across firms in a given industry. The figure shows that in a given industry the most-productive firms outsource in the South while the least-productive firms integrate in the North. Firms with intermediate productivity levels either outsource in the North or integrate in the South.

Figure 1 portrays a complementarity between the ownership structure and the location of production: in an industry in which a larger fraction of firms engage in outsourcing, a larger fraction of firms source their intermediate inputs in the South. The broken line depicts the boundary along which firms are indifferent between manufacturing intermediate inputs in the South and in the North. This line is upward-sloping for an intermediate range of fO, implying that the share of entrepreneurs who choose M agents in the South is larger, the smaller is the fixed cost of outsourcing. Therefore, cross-industry variation in the fixed cost of outsourcing generates a positive correlation between outsourcing and the sourcing of intermediate inputs in the South.

B. Complementarity II

We now extend the model to allow for costly transport of intermediate inputs. To make this analysis interesting, we allow F to locate assembly in the South or in the North. But we continue to assume that F controls the assembly activity (i.e., that assembly is integrated with product design). Then the only new option available to F is to conduct FDI in assembly, which entails an extra fixed cost of g^S > 0. This extra cost means that F has no reason to locate assembly in the South unless it is costly to transport intermediate inputs. Thus, the introduction of an FDI option would not matter without the assumption of costly transport.

Transport costs take the “iceberg” form. A firm must ship τ > 1 units of the intermediate input from the South in order that one unit arrives in the North. Bargaining takes place after the intermediate inputs have arrived at their destination. Therefore, the effective marginal cost of producing intermediates in the South for delivery in the North is τω^S. The operating profits for a firm that assembles final goods in country j, produces intermediates in country ℓ, and has an ownership structure k are given by

$$\pi_{j,\ell}^{k}(\Theta) = D^{\frac{1}{1-\alpha}}\Theta T_{j,\ell}^{k} \psi_{j,\ell}^{k} - f_{j,\ell}^{k} - g_{j,\ell}^{k}$$
where $g^I_k = g^O_k = g^S > 0$, $g^N_k = g^N_O = 0$,

$$T^{j, \ell} = \begin{cases} \tau^{-(1-\eta)/(1-\alpha)} & \text{if } j \neq \ell \\ 1 & \text{otherwise} \end{cases}$$

and

$$\psi^{j, \ell}_k = \frac{1 - \alpha[\beta_k \eta + (1 - \beta_k)(1 - \eta)]}{\left(\frac{1}{\alpha}\left(\frac{w^j}{\beta_k}\right)^{\eta} \left(\frac{w^\ell}{1 - \beta_k}\right)^{1-\eta}\right)^{\alpha/(1-\alpha)}}.$$ 

This leaves us with eight potential organizational forms, indexed by \( \{k, \ell, j\} \), where \( k = I \) or \( O \), \( \ell = N \) or \( S \), and \( j = N \) or \( S \). As before, \( k \) represents the ownership structure and \( \ell \) represents the location of \( M \), while the new index \( j \) represents the location of assembly.

To economize on the number of cases, we assume that \( \tau \) is large, so that separation of production of intermediate inputs and assembly by \( F \) never is profitable. Then \( F \) chooses an organizational form from among the remaining alternatives, which are \( \{O, N, N\} \), \( \{I, N, N\} \), \( \{O, S, S\} \), and \( \{I, S, S\} \).

We show in our working paper that Figure 2 depicts the equilibrium choices. For a fixed \( f^S \), the most-productive firms outsource the production of intermediate inputs in the South and assemble final goods abroad, while the least-productive firms produce intermediate inputs in-house and perform all activities in the North. In industries with lower fixed costs \( f^S \), a larger fraction of firms source their intermediate inputs and conduct assembly in the South, and a larger fraction of firms outsource the production of parts. We have thus identified another complementarity between outsourcing and offshoring. As in Grossman et al. (2004a), the manufacturing of intermediate inputs and assembly gravitate to the same country as a means to conserve on transportation costs. While it is more profitable to locate these activities in the South the lower is the fixed cost \( f^S \), lower \( f^S \) also makes outsourcing more profitable, because production in the South reduces unit cost and makes it profitable to produce a larger volume of output. When large quantities are desirable, outsourcing is attractive, because manufacturers have better incentives to produce parts. It follows that variations in the fixed cost of foreign sourcing produce a positive correlation between the fraction of firms that outsource and the fraction that source their intermediate inputs in the South.

Finally, we note that a very similar figure would apply if we were to consider variation in integration strategies as a function of the fixed cost \( g^S \), instead of the cost \( f^S \). Both parameters reflect the cost of doing business in the South. Given that manufacturing and assembly are always located in the same country due to high transport costs for intermediate inputs, the roles played by the fixed costs associated with these two activities are similar.
